The average patient is young, male and black, and usually arrives by ambulance. Only a third of the patients who seek treatment at Rescue 81 receive a psychiatric diagnosis. A report published in the New England Journal of Medicine in December showed that a first time treatment with a cognitive behavioral therapy intervention called METT-HEP (Meta-Analysis of treatment for suicidal behaviors in high-risk patients) decreased by nearly 50 percent the chance of suicide within a month of treatment. It also showed that a longer course of treatment had a greater impact, increasing the chances of not repeating the suicide attempt by 70 percent. “This is a high-risk service,” said Dr. Bonnie Lesperance, an emergency physician who leads the mental health team. “We’re not talking about regular suicidal patients who are just having a bad day. These are people who have come in to the emergency department who have tried and tried to do something to kill themselves, and unfortunately we have saved a lot of lives using this approach.” The cognitive behavioral therapy techniques center on behavior and attitude. For instance, it can help patients deal with self-destructive thoughts. “If someone thinks about harming themselves, instead of focusing on the thoughts, we ask them to do something else like make a shopping list,” said Dr. Lesperance. The intervention is based on a previous research project that was carried out by Columbia University’s Center for the Treatment and Study of Suicide and the National Institute of Mental Health f3916c5595

The hypothesis of this proposal is that the EGF receptor is a poor indicator of tumor metastasis. We will test this hypothesis using three different metastatic models: the immunosuppressed mouse, the B16 melanoma, and the Lewis Lung Carcinoma. The first three Specific Aims of this proposal are: 1) We will determine the optimal amount of EGF to administer in order to maximize the metastatic potential of the mouse tumor cell lines in the lung. 2) We will determine if there is an age related difference in the sensitivity of normal and tumor bearing mice to the effects of EGF. 3) We will determine if the administration of EGF during the first three days of a mouse's life can induce premature birth in the mouse lung. The final two Aims of this proposal are: 1) We will determine the ability of immunotherapy to modulate the effects of EGF on metastasis. 2) We will determine if EGF produces different results in the lung than in the spleen. These aims will be accomplished by assaying tumor colonies in the lungs of tumor bearing animals.
